

Investment concentration and financing in the AI boom

Abstract

Financing conditions at the project margin need not characterise an investment boom when investment is concentrated. Among the 500 largest U.S. public companies, incremental operating cash flow covers 117% of the 2022–2025 investment increase at the five largest investors and 102% at the top ten, which account for 52.8% of it, but –61% across the remaining 213 firms. The pattern is not a mechanical consequence of concentration: the more concentrated 2018–2021 window instead has the tail as its best-covered group. For firms making more than half the increase, incremental internal cash was itself sufficient to cover it.

Keywords: investment concentration, internal finance, artificial intelligence, corporate investment, aggregation

JEL: G31, G32, E22, O32

1. Introduction

Among the 500 largest U.S. public companies, incremental operating cash flow over 2022–2025 covers 117% of the incremental capital expenditure of the five largest investors and 102% of that of the top ten, which account for 52.8% of the positive increment, but –61% across the remaining 213 firms with rising investment (Table 1). The five—Alphabet, Amazon, Oracle, Meta and Microsoft, selected mechanically as those with the largest absolute increase in real capital expenditure—carry 38.9% of that increment on their own.

Such a gradient matters because financing evidence gathered at the project margin need not characterise the investment-weighted aggregate. Recent work documents the artificial-intelligence buildout being financed through private credit, infrastructure funds, off-balance-sheet vehicles and hardware-collateralised lending, and asks what the exposures imply for financial stability (Van Nieuwerburgh, 2026). That evidence describes particular projects and particular firms. Because an aggregate is a capital-expenditure-weighted sum, it is dominated by wherever the incremental spending occurred, and here the incremental spending is extraordinarily concentrated: the Herfindahl index of capital expenditure within the 500 rises from 173 in 2021 to 309 in 2025, while excluding the five largest spenders it moves only from 95 to 104. That a few firms can dominate an aggregate is the granular mechanism of Gabaix (2011), Carvalho and Gabaix (2013) and di Giovanni et al. (2014); we apply it to financing rather than to fluctuations.

Investment concentration and firm-level covariation between internal funds and investment are both established (Grullon et al., 2018; Gutiérrez and Philippon, 2017; Fazzari et al., 1988; Kaplan and Zingales, 1997; Myers and Majluf, 1984). We document the alignment between them during this boom and show it is historically unusual, as an accounting decomposition of realised flows rather than a causal test.

2. Data and methods

Firm-level data are constructed from the SEC’s XBRL *frames* interface for 2013–2025 and reconciled to the underlying filings. The construction unions alternative tags: filers do not use a single tag for a given concept, and a single-tag series would omit Amazon, the largest U.S. capital spender, together with 454 other firms accounting for \$404 billion of 2025 capital expenditure (Appendix A, Table A2). We measure the buildout using total capital expenditure, following Soto et al. (2026) and Van Nieuwerburgh (2026).

The universe is the 500 U.S. registrants with the largest fiscal-2024 revenue, excluding non-filers. The universe excludes private firms by construction. Figures are deflated to 2025 dollars using the BLS producer price index for private capital equipment (WPUFD41312).

The exercise cumulates incremental flows rather than comparing two annual observations. For each series X and firm i ,

$$\Delta X_i = \sum_{t=2022}^{2025} (X_{it} - \bar{X}_i), \quad (1)$$

$$\text{Coverage}_i = \frac{\Delta \text{OCF}_i}{\Delta \text{CAPEX}_i}, \quad (2)$$

where $\bar{X}_i$ is either the 2021 value (baseline A) or the 2017–2021 average (baseline B).

Let $s_i = \Delta \text{CAPEX}_i / \sum_j \Delta \text{CAPEX}_j$ be firm i ’s share of the aggregate increment. Then

$$\text{Coverage}_G = \sum_i s_i \text{Coverage}_i, \quad (3)$$

so an aggregate coverage ratio is the increment-weighted mean of firm-level coverage. A group’s aggregate therefore places greatest weight on its largest incremental investors, whatever the coverage of the remaining firms in it.

The ratio requires an observed baseline as well as a positive denominator: a firm absent in 2021 would otherwise be assigned a baseline of zero, making its entire subsequent spending appear incremental. Of the 500, 404 report capital expenditure at both endpoints: 263 have a positive cumulative increment and 141 do not. The remaining 96 lack an observation at one or both endpoints, 17 of them reporting 2025 spending with no 2021 baseline, which would otherwise enter as \$28 billion of spurious increment. Firms whose investment fell are excluded rather than assigned a signed ratio.

The five focal firms are selected mechanically from financial statements, not from AI disclosures; Appendix A, Table A1, records what each firm’s own filings say, including cases where the capex–AI attribution is only partial. Coverage above 100% establishes that internally generated cash grew by more than investment did, not that particular dollars financed particular assets. Every reported number is produced from frozen, hashed source files by a single script, and the manuscript is gated against the resulting claims file.

3. Results

3.1. A historically unusual rank–coverage gradient

Table 1 reports the central result. Ranking the 263 firms with rising investment by their cumulative incremental capital expenditure traces a rank–coverage gradient: internal cash coverage peaks at the five largest investors and then falls at every successive cut, from 117%

for the top five to -61% for the remaining 213. The top ten firms account for 52.8% of positive incremental capital expenditure at 102% coverage. The top-five figure is not one firm’s doing: coverage remains at least 79% omitting any single one of them.

The positive-increment restriction affects only the tail. Coverage at every cut through the top fifty is invariant to it, because those cuts contain the same firms either way; admitting the 141 firms whose investment fell, with signed increments, raises the top-five share of the increment from 38.9% to 46.0% and leaves the gradient steeper, not weaker.

Concentration and internal financing are not the same phenomenon. The 2018–2021 window was more concentrated at the top than 2022–2025—a top-five share of 41.9% against 38.9% —yet its rank pattern runs the other way: the tail is its best-covered group, as it is in 2014–2017 (Table 2). Concentrated investment booms are not internally financed booms as a rule. What is unusual about the present one is that the two coincide.

Three checks bound the top-five aggregate. First, the baseline: on the 2017–2021 average the corresponding figures are \$757 billion, \$587 billion and coverage 129% , so both baselines give the same answer. Second, dependence on one firm: coverage ranges from 79% (omitting Amazon) to 135% (omitting Alphabet) and exceeds 100% in four of the five cases. Third, dispersion within the group: firm-level coverage runs from 63% at Alphabet and 64% at Oracle to 118% at Microsoft and 361% at Amazon, which is why the cumulative ratio is not monotone across the first three cuts— 63% , then 68% , then 117% —and why sufficiency is a property of the group aggregate and not of every constituent (Appendix A, Table A3). Coverage is also an end-of-period property: cumulated from the 2021 baseline it is -39% through 2022 and reaches 117% only in 2025 (Figure 1c).

3.2. *The gradient survives sector exclusions*

One concern is that the tail contains regulated, extractive and financial firms whose cash-flow economics differ from the rest of the sample. Excluding these groups does not attenuate the gradient. The 25 regulated and extractive firms in the tail are its best-covered part, at 122% coverage on 19.9% of tail investment, and the 25 financial firms cover 298% . The tail’s -61% comes from the other 163 firms, which carry 73.0% of tail investment at -146% coverage. Dropping regulated, extractive and financial firms from the sample altogether leaves the gradient intact and steeper: 117% at the top five, 97% at the top ten, 80% at the top fifty and -324% across the remainder (Appendix A, Table A3). An AI-intensity cut built from 10-K text without reference to any financing outcome gives the same answer (Appendix A, Table A1).

3.3. *Limitations*

Three bound the reading. (i) The sample selects on an observed 2021 baseline and on a positive increment; Section 3.1 reports what relaxing the second does. (ii) Coverage is an accounting relation between realised flows, not a financing statement: it does not trace particular dollars to particular assets and identifies no counterfactual of firm behaviour. (iii) The universe is large public filers, so private firms and special-purpose vehicles lie outside it by construction.

4. Conclusion

The financing of marginal projects need not characterise an investment boom in the aggregate: during the AI buildout, internal cash coverage falls from 117% at the five largest incremental

Table 1: Internal cash coverage of incremental investment, cumulative flows 2022–2025

	Firms	Share of increase (%)	Coverage (%)
Top 1	1	10.2	63
Top 3	3	26.5	68
Top 5	5	38.9	117
Top 10	10	52.8	102
Top 20	20	64.3	82
Top 50	50	81.7	53
Remaining firms	213	18.3	−61

Notes. Sample: the 263 firms among the 500 largest U.S. registrants by fiscal-2024 revenue that report capital expenditure in both 2021 and 2025 and whose cumulative incremental capital expenditure over 2022–2025 is positive; their aggregate incremental capital expenditure is \$941 billion. Increments follow equation (1) and coverage equation (2). Shares are of that \$941 billion. Amounts in billions of 2025 dollars, deflated by BLS series WPUFD41312. On the 2017–2021 average baseline the top five show coverage of 129%.

Table 2: Internal cash coverage by investment rank, earlier four-year windows

	2022–25	2018–21	2014–17
Top 5	117	176	186
Top 10	102	159	181
Top 20	82	127	158
Top 50	53	136	152
Remaining firms	−61	548	193
Top-5 share of increase	38.9	41.9	21.0

Notes. Coverage in percent, computed as in Table 1, on the same construction and baseline convention. Each window uses its own baseline year (2021, 2017 and 2013) and its own sample of firms with positive cumulative incremental capital expenditure over the four years following.

Figure 1: (a) Capital expenditure as a share of operating cash flow, the five largest incremental investors, 2017–2025. (b) Herfindahl index of capital expenditure among the 500 largest U.S. public companies by revenue, with and without those five firms. (c) Coverage of the increment cumulated from the 2021 baseline through each year, the five against all other sample firms.

investors to -61% across the remaining 213. The gradient is specific to this boom, absent in the preceding two four-year windows including the more concentrated 2018–2021.

This reconciles, rather than contradicts, evidence on external financing: project-finance structures lie largely outside our sample. For the firms making more than half the increment, incremental internal cash was in aggregate sufficient to cover their part of the boom, so the headline size of the investment boom overstates the amount of incremental investment for which incremental internal cash was insufficient. The result is time-specific; capital expenditure absorbed 70% of the five firms’ operating cash flow in 2025 against 31% in 2017, so internal financing slack narrowed sharply over the sample.

Declaration of competing interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Data availability

The replication archive is deposited on Zenodo ([DOI PENDING]) and contains the frozen source files, the collection and analysis code, the machine-generated claims file against which every reported number is checked, a SHA-256 manifest of every archived file, a one-command verification script, and a companion document describing the archive in full. Firm-level data were retrieved on 2–4 September 2026 from the SEC’s XBRL *frames* interface, one call per tag and year, at <https://data.sec.gov/api/xbrl/frames/us-gaap/<tag>/USD/CY<year>.json>; 10-K text and registrant classifications come from EDGAR and the submissions API (<https://www.sec.gov/edgar/sec-api-documentation>). The tags unioned for each series, including capital expenditure and operating cash flow, are listed in `code/engine.py`. The deflator is Bureau of Labor Statistics series WPUFD41312, final demand–private capital equipment, annual averages [DEFLATOR RETRIEVAL]. The *frames* interface returns the most recently filed value for each fact, so a later retrieval may differ where filers have restated; the frozen copies in the archive are the basis for every figure reported here.

Declaration of generative AI and AI-assisted technologies in the manuscript preparation process

During the preparation of this work the authors used Claude (Anthropic) for code scaffolding, code review, minor grammatical edits and readability improvements. The tool was not used to generate, analyse or alter any datum, estimate, table or figure: all results are produced by the deposited scripts from the frozen source files. After using this tool the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

Appendix A. Supplementary evidence

Table A1. AI attribution and AI-exposure robustness

<i>Panel A. What the five firms' own filings say</i>			
Firm	Filing	Evidence	Capex–AI link
Alphabet	10-K FY2025	“capital expenditures as we scale our technical infrastructure, in particular for AI”	Explicit
Meta	10-K FY2025	“servers, data centers, and network infrastructure”; 2026 capital expenditure “to support our AI efforts”	Explicit
Microsoft	10-K FY2026	“capital expenditures to support growth in our cloud offerings and our investments in AI training”	Explicit
Oracle	10-K FY2026	“multi-year commitments for excess data center space and related capital expenditures”; not AI-explicit	Partial
Amazon	10-K FY2025	cash capital expenditure “primarily reflect[s] investments in technology infrastructure (the majority of which is to support AWS business growth)”; not AI-explicit	Partial

<i>Panel B. Coverage among firms ranked by AI intensity in their 10-K</i>			
	Firms	Share of increment (%)	Coverage (%)
Top decile	26	41.9	126
Top quintile	52	43.6	131

The five firms are selected mechanically from financial statements, not from AI disclosures. AI intensity is occurrences of a pre-specified AI dictionary per 10,000 words of the firm’s most recent 10-K, with top-decile and top-quintile cutoffs of 2.25 and 1.35 fixed before any financing result was computed (Loughran and McDonald, 2011; Hoberg and Phillips, 2016; Ante and Saggu, 2025). The five largest investors account for 92.8% of the top decile’s incremental capital expenditure, so Panel B is a relabelled sample rather than an independent one. Full dictionary, filing accession numbers and scoring code are in the replication archive.

Table A2. Data construction and validation

	Count	
Observations reconciled (5 firms, 7 series, 2 years, where reported)	49	
Exact match to originally filed value	48	98%
Later filing uses gross-purchase presentation	1	Meta capital expenditure 2021
Unexplained discrepancies	0	

Each constructed observation for the five focal firms is matched to a 10-K-reported value for the same fiscal period. The sole non-identical observation is Meta’s 2021 capital expenditure. The FY2021 filing reports \$18.567bn, while the later FY2022 filing presents \$18.690bn of gross purchases of property and equipment alongside \$123m of related proceeds. The SEC interface returns the later gross-purchase presentation, which our series uses. Microsoft’s fiscal year ends in June and Oracle’s in May: Microsoft’s 2025 observation covers July 2024 to June 2025 and Oracle’s runs to May 2026, so the two windows fall either side of the December endpoint used for the other three. We retain the SEC convention. Capital expenditure and operating cash flow are unions of alternate tags; a single-tag capital-expenditure series would omit Amazon and 454 other filers representing \$404 billion of 2025 spending. Deflator: BLS PPI WPUFD41312. All source files are frozen and SHA-256 hashed, and every number is verified against a machine-generated claims file by an automated build gate.

Table A3. Firm-level and sectoral robustness

<i>Panel A. The five largest incremental investors</i>			
Firm	ΔCapex	ΔOCF	Coverage
Alphabet	96	61	63%
Meta	81	63	77%
Oracle	73	46	64%
Microsoft	67	79	118%
Amazon	49	177	361%
<i>Leave-one-out: group coverage with the named firm omitted</i>			
Omitted firm	ΔCapex	ΔOCF	Coverage
Omit Alphabet	270	366	135%
Omit Meta	285	364	128%
Omit Oracle	293	380	130%
Omit Microsoft	299	347	116%
Omit Amazon	317	249	79%

	Firms	Share of tail (%)	Coverage (%)
<i>Panel B. Composition of the 213-firm tail</i>			
Regulated and extractive	25	19.9	122
Financial	25	7.1	298
All other	163	73.0	-146
<i>Panel C. Coverage by rank, dropping regulated, extractive and financial firms</i>			
Rank group	Firms		Coverage (%)
Top 5	5		117
Top 10	10		97
Top 20	20		90
Top 50	50		80
Remaining	133		-324

Cumulative incremental flows, 2022–2025, baseline A (2021), billions of 2025 dollars. Coverage is formed from unrounded flows, so it need not reproduce exactly from the rounded columns shown. Panels B and C classify registrants by the SIC code in their own SEC filing: regulated and extractive is oil and gas extraction, refining, rail, water and air transport, pipelines and utilities; financial is banks and insurers, whose operating cash flow is not a comparable object. Panel C drops both groups, leaving 183 firms.
